

17| Differences Between ArrayList and LinkedList in Java.

| ArrayList | LinkedList |
|---|---|
| 1. $O(1)$ (Direct indexing) | 1. $O(n)$ (sequential traversal) |
| 2. Amortized $O(1)$ (Occasional resize) | 2. $O(1)$ (Direct append) |
| 3. $O(n)$ (shifting required) | 3. $O(1)$ (If node reference is known, otherwise $O(n)$) |
| 4. Less overhead (array only) | 4. More overhead (extra references) |
| 5. Search contains $O(n)$ | 5. Search contains $O(n)$ |

↳ (if $O(1)$ traversal and shifting is fine)

When to use which?

- Use ArrayList when:
 - You need fast random access ($O(1)$ lookup).
 - ~~Intense~~ Insertions / deletions infrequent.
 - Memory efficiency is a priority.

Use linked list when:

frequent insertions / deletions in the middle are required.

- Sequential access is preferred over random access.
- Memory overhead is not a concern.

18. Random Generation

```
import java.util.Random;
import java.util.Arrays;
```

```
public class CustomRandomGenerator {
    private static final int[] SEED_ARRAY = {3, 7, 11,
                                             17, 23};
    public static int myRand(int n) {
        long timestamp = System.currentTimeMillis();
        int seed = SEED_ARRAY[(int)(timestamp % SEED_ARRAY.length)];
        return (int)((timestamp * seed) % n);
    }
}
```

11/20/13

```
public static int[] myRand(int n, int count) {
    int[] randomNumbers = new int[count];
    for (int i = 0; i < count; i++) {
        randomNumbers[i] = myRand(n);
    }
    return randomNumbers;
}
```

```
public static void main (String [] args) {
    System.out.println ("Single random number: " + myRand
    System.out.println ("Multiple random numbers: " + Arrays.
    (myRand (100, 5)));
}
```

19) Multithreading in Java

Multithreading in java allows multiple threads to run concurrently, improving performance and responsiveness. Java provides built-in support - through the Thread class and Runnable interface.

Thread Class vs Runnable Interface

1. Thread Class - Extending Thread requires overriding the run() method but prevents extending other classes.
2. Runnable Interface - Implementing Runnable allows better flexibility, enabling the class to extend other classes.

Example:

```
Class MyThread extends Thread {
    public void run () { system.out.println ("thread
using Thread class"); }
}
```

```

class MyRunnable implements Runnable {
    public void run () { System.out.println ("Thread using
        Runnable interface"); }
}

public class ThreadExample {
    public static void main (String [] args) {
        new MyThread ().start ();
        new Thread (new MyRunnable ()).start ();
    }
}

```

Potential Issue in Multithreading

- Race Condition - Multiple threads modifying data simultaneously, causing inconsistencies.
- Deadlocks - Two or more threads waiting for each other to release resources.
- Starvation - Low-Priority threads not getting CPU time.
- Livelock - Threads continuously responding to each other without making progress.

using synchronized for Thread Safety

The synchronized keyword prevents multiple threads from accessing exact critical code simultaneously.

Example

Class SharedResource {

 private int count = 0;

 public synchronized void increment() { count++; }

 public synchronized int getCount() { return count; }

Deadlock Scenario

Class Resource {

 void methodA(Resource r) {

 synchronized (this) {

 System.out.println(Thread.currentThread().getName() +

 " locked resource 1");

 synchronized (r) {

Ring-Buffer Mechanism - Use `trylock()` from `ReentrantLock`
instead of `Synchronized` or `Atomic` {atomic class}

Implementation of Ring Buffer

```
public class RingBuffer<T> {
    private final ReentrantLock lock = new ReentrantLock();
    private final Condition notFull = lock.newCondition();
    private final Condition notEmpty = lock.newCondition();
    private final T[] array;
    private int size;
    private int head;
    private int tail;

    public RingBuffer(int capacity) {
        array = (T[]) new Object[capacity];
        size = 0;
        head = 0;
        tail = 0;
    }

    public void put(T value) throws InterruptedException {
        lock.lock();
        try {
            while (size == array.length)
                notFull.await();
            array[tail] = value;
            tail = (tail + 1) % array.length;
            size++;
            notEmpty.signal();
        } finally {
            lock.unlock();
        }
    }

    public T get() throws InterruptedException {
        lock.lock();
        try {
            while (size == 0)
                notEmpty.await();
            T value = array[head];
            head = (head + 1) % array.length;
            size--;
            notFull.signal();
            return value;
        } finally {
            lock.unlock();
        }
    }
}
```

```
    finally { lock2.unlock(); }  
  }  
  finally { lock1.unlock(); }  
}  
}
```

↳ **Reentrant Lock**: A lock which can be re-acquired by the same thread.

↳ **Non-Reentrant Lock**: A lock which cannot be re-acquired by the same thread.

↳ **Reentrant Lock Implementation**:

```
class ReentrantLock {  
    private int count = 0;  
  
    public void lock() {  
        count++;  
    }  
  
    public void unlock() {  
        count--;  
    }  
}
```

↳ **Non-Reentrant Lock Implementation**:

```
class NonReentrantLock {  
    private boolean locked = false;  
  
    public void lock() {  
        if (!locked) {  
            locked = true;  
        } else {  
            throw new RuntimeException("Lock already held");  
        }  
    }  
  
    public void unlock() {  
        if (locked) {  
            locked = false;  
        } else {  
            throw new RuntimeException("Lock not held");  
        }  
    }  
}
```

201

Exception Handling in Java (short overview)

Exception handling in Java ensures that runtime errors do not disrupt program flow. It is managed using try, catch, finally, throw, and throws key words.

Checked vs Unchecked Exceptions

- Checked Exceptions: Checked at compile-time; must be handled using try-catch or declared with throws.
- Unchecked Exceptions: Occur at runtime; typically caused by programming errors.

Creating & Throwing Custom Exceptions

- Extend Exception for checked exceptions or RuntimeException for unchecked exceptions.
- Use throw to explicitly throw an exception.

(Invisible code) and no facilities exists
to class, CustomException extends Exception {

 public CustomException (String message)

```
{  
    super (message);  
}
```

}

throw new CustomException ("Custom checked
exception");

Role of throw and throws

- throw : Used to manually throw an exception.

- throws : Declares, exceptions a method might
throw.

public void method () throws IOException {

 throw new IOException ("Error occurred") ;

}

PreventingPreventing Resource Leaks

- Use finally Block: Ensures resources are closed.
- Try-with-Resources (AutoCloseable): Java 7+ automatically closes resources.

```
try (FileInputStream file = new FileInputStream("file.txt")) {  
}  
} catch (IOException e) {  
    e.printStackTrace();  
}
```

Q21

Interfaces in Java can have default methods starting from Java 8, and this feature introduces some interesting distinctions when compared to abstract classes'.

Interfaces with default Methods :

- Interfaces can have both abstract methods and default methods.
- Default methods allow you to add functionality to an interface without breaking existing implementations.
- Since interfaces can have no state, they can only provide behavior or constants.

Abstract classes:

- Abstract classes can hold both state (instance variable) and behaviour (method).
- They can have constructors, non-static fields, and concrete methods.

Conflicting Method Implementations between abstract classes and interfaces:

If both an abstract class and interface provide conflicting method implementations, the concrete class must explicitly resolve the conflict by overriding the method.

example code :

```
interface A {
```

```
    default void hello() {
```

```
        System.out.println("Hello from A");
```

```
}
```

```
}
```

```
abstract class B implements A {
```

```
    @Override
```

```
    public void hello() {
```

```
        System.out.println("Hello from B");
```

```
}
```

```
class C extends B {
```

```
    @Override
```

```
    public void hello() {
```

```
        System.out.println("Hello from C");
```

```
}
```

```
}
```

IT²3013

(2)

| Feature | Hashmap | Tree map | LinkedHashMap |
|--------------------|----------------------------------|--|--------------------------------------|
| Internal Structure | Hash table | Red black tree | Hash Table + Doubly linked List |
| Order of Elements | No order guaranteed | Sorted | Insertion order |
| Insertion time | $O(1)$ | $O(\log n)$ | $O(1)$ |
| Deletion time | $O(1)$ | $O(\log n)$ | $O(1)$ |
| When to use | Fast access with no order needed | When you need sorted keys or range queries | When you need insertion/access order |

How does TreeMap differ from HashMap in ordering

- HashMap does not maintain any order of its keys

The order in which you iterate over the keys or entries can be arbitrary.

- TreeMap, on the other hand maintains a sorted order of the key based on their natural ordering or a comparator, meaning the elements will be traversed in ascending order by default

• Ascending order by default is based on natural ordering.

• Natural ordering is based on the class hierarchy.

• Step 1: Sort the keys based on natural ordering.

• Step 2: Insert the elements into the tree.

• TreeMap is implemented using Red Black Tree.

23

Static Binding and Dynamic Binding in java and their relation to polymorphism.

Static Binding : Occurs when the method call is resolved at compile-time. This happens when the method being invoked is determined based on the type of the reference. Static methods, private method, and final methods are examples of methods that are statically bound.

Dynamic Binding : Occurs when the method call is resolved at runtime, based on the actual object type, not the reference type. This is a key feature of runtime polymorphism.

Methods overridden in subclasses are dynamically bound.

Static binding Example :

a. animal.sound();

b. animal.bark();

24

Advantages of ExecutorService over Manual Thread Management:

1. Thread Pool management.

2. Automatic thread reuse.

3. Task scheduling.

4. Graceful shutdown.

5. Errors Handling and Monitoring.

Benefits of using Callable over Runnable.

Runnable :

- *. Runnable tasks are designed to perform an action but do not return any result. It is ideal when you simply want to execute some code without needing any feedback.
- *. Runnable cannot throw checked exceptions directly; they must be wrapped in a try-catch block.

Callable :

- *. Callable is similar to Runnable but can return a result. This is useful when you need the outcome of the task or need to compute a value.

* Callable can throw checked exceptions, which means you can propagate exceptions from the task directly.

Differences between `submit()` and `execute()` Methods.

① execute method :

- * This method is used to submit a runnable task to the ExecutorService. The `execute()` method doesn't return any result or feedback. It only signals that the task has been submitted for execution.
- * It doesn't provide a way to handle exception thrown by the task.

submit method

* The submit method is more versatile than execute.

It allows you to submit both runnable and callable tasks.

submit() returns two() threads, one for submitted tasks.

tasks to the ExecutorService.

If the task throws an exception, it can be retrieved through the future object.

start() or run() of both of them still work.

both of them will be destroyed after start() or run().

Both of them are thread-safe.

85

code:

```

class NegativeRadiusException extends Exception {
    public NegativeRadiusException(String message) {
        super(message);
    }
}

public class Circle {
    private double radius;
    public void setRadius(double radius) throws NegativeRadiusException {
        if(radius < 0) {
            throw new NegativeRadiusException("Radius cannot be negative.");
        }
        this.radius = radius;
    }
}

public static void main(String[] args) {
    Circle circle = new Circle();
}

```

try {

circle.setRadius(-5);

System.out.println("Area of circle: " + circle.calculateArea());}

catch(NegativeRadiusException e){

System.out.println("Error: " + e.getMessage());

}

try {

circle.setRadius(0);

System.out.println("Area of circle: " + circle.calculateArea());

}

catch(NegativeRadiusException e){

System.out.println("Error: " + e.getMessage());

}

{

}

26. There are two primary ways to create a thread:

1. By implementing the runnable interface.
2. By extending the thread class.

Creating a thread using the runnable interface:

```
class MyRunnable implements Runnable {
```

@Override

```
public void run() {
```

```
System.out.println("Thread is running Runnable  
Interface!");
```

}

```
public class RunnableExample {
```

```
public static void main(String[] args) {
```

```
MyRunnable myRunnable = new MyRunnable();
```

```
Thread thread = new Thread(myRunnable);
```

```
thread.start();
```

}

Creating a thread by extending the Thread class;

class MyThread extends Thread {

@Override

public void run() {

System.out.println("Thread is running by
extending Thread class!");

}

public class ThreadExample {

public static void main(String[] args) {

MyThread myThread = new MyThread();

myThread.start();

}

}

28/1

Java's garbage collection (GC) is responsible for automatically managing memory by reclaiming the memory that is no longer in use. Java uses automatic memory management, which helps developer focus on logic without having to manually allocate memory. The goal is to find and remove objects that are no longer referred by the program, freeing up memory to be reused.

phases of Garbage Collection :

1. Mark Phase : The GC identifies all objects that are reachable.
2. Sweep phase : The GC removes objects that are not reachable (no references).

3. Compact Phase: The GC may move objects in memory to eliminate gaps, allowing more efficient memory usage.

After this phase, the heap is typically organized into a contiguous block of memory, which makes it easier to manage and reuse.

Memory management systems often implement a combination of copying and compacting phases to handle different types of memory fragmentation.

Copying involves moving objects from one part of memory to another, while compacting involves shifting objects to fill gaps in memory.

Both techniques have their pros and cons, and the choice between them depends on the specific requirements of the application.

Memory management is a complex topic, but understanding its basic principles can help you optimize your application's performance and reduce memory leaks.

Memory management is also critical for mobile applications, where memory constraints are often more stringent than on desktop systems.

By learning how to effectively manage memory in your applications, you can ensure that they run smoothly and efficiently, even on devices with limited resources.

Memory management is a complex topic, but understanding its basic principles can help you optimize your application's performance and reduce memory leaks.

Memory management is also critical for mobile applications, where memory constraints are often more stringent than on desktop systems.

29/code:

```

import java.io.*;
import java.util.Scanner;

public class HighestvalueAndSum {
    public static void main (String [] args) {
        String inputFile = "input.txt";
        String outputFile = "output.txt";
        int highestValue = Integer.MIN_VALUE;
        int sum = 0;
        try (Scanner scanner = new Scanner (new F
                                         inputfile))) {
            while (scanner.hasNextInt ()) {
                int number = scanner.nextInt ();
                sum += number;
                if (number > highestValue) {
                    highestValue = number;
                }
            }
        }
    }
}

```

```

    catch(FileNotFoundException e){
        System.out.println("The input file was not found.");
        return;
    }

    try(PrintWriter writer = new PrintWriter(new File(outputfile)))
    {
        writer.println("Highest Value : " + highestValue);
        writer.println("Sum : " + sum);
        System.out.println("Results written to " + outputFile);
    }
    catch(FileNotFoundException e){
        System.out.println("Error writing to the output file.");
    }
}

```

Method D implemented in Main Class
Method E implemented in Main Class)

37

Issue with the code

The class Z implements both interfaces X and Y, but both interfaces contain a default method show().

This results in a "duplicate default method" conflict, leading to a compilation error because Java does not know which show() method to inherit.

Solution 1: Override the show() method in class Z

```
public class Z implements X, Y {
    @Override
    public void show() {
        X.super.show(); // Explicitly calling show() from interface X
    }
}
```

```
public static void main(String[] args) {
    Z obj = new Z();
    obj.show();
}
```

Solution 2

public class Z implements X Y {

@Override

public void show() {

System.out.println("Z's own show method");
}

public static void main(String[] args) {

Z obj = new Z();

obj.show(); // calls overridden show() from Z

381

```
Class SingletonExample {
```

```
    private static SingletonExample instance;
```

```
    private SingletonExample() {
```

```
        System.out.println("SingletonExample instance created.");
```

```
}
```

```
    public static synchronized SingletonExample getInstance() {
```

```
        if (instance == null) {
```

```
            instance = new SingletonExample();
```

```
}
```

```
        return instance;
```

```
}
```

```
    public void showMessage() {
```

```
        System.out.println("Hello from SingletonExample");
```

```
}
```

```
public class SingletonDemo {
```

```
    public static void main(String[] args) {
```

```
        SingletonExample obj1 = SingletonExample.getInstance();
```

```
        SingletonExample obj2 = SingletonExample.getInstance();
```

```
        obj1.showMessage();
```

```
        if (obj1 == obj2) { System.out.println("Both are same instance"); }
